ON MAKING THE SHORTLIST
FOR THE SELECTION OF CANDIDATES

by

Ingram Olkin and Michael A. Stephens

1. INTRODUCTION

Bias in the selection of candidates for employment or for the admission to college has been an issue of considerable public interest. Although there may be general consensus on the existence of bias, there is little consensus on a definition of bias, and indeed there are a variety of definitions. Cole (1973) provides an extensive exposition of a number of definitions that are known by the names quota model, regression model, equal risk model, constant ratio model, conditional probability model. We describe but one of these models in order to establish how our analysis differs from these.

In the constant ratio model Thorndike (1971) proposed a definition of fairness. Suppose there are two groups A and B , a predictor variable X , and a criterion variable Y . The model requires that the success ratio be equal to the selection ratio. This model is implemented in the following way. Let X_A and X_B denote selection cutoff points to be determined for the two groups, and let c denote the given passing cutoff point on the criterion. The first requirement is that the equality

$$(1) \quad \frac{P_A\{Y > c\}}{P_B\{Y > c\}} = \frac{P_A\{X > X_A\}}{P_B\{X > X_B\}}$$

hold.

If we are to select a total of N applicants, where N_A and N_B are the number of applicants in groups A and B , respectively, then we simultaneously solve (1) and

$$(2) \quad N_A P_A\{X > X_A\} + N_B P_B\{X > X_B\} = N.$$

for X_A and X_B for a given passing cutoff point c . Often these computations are made with the assumption that in each group (X, Y) has a bivariate normal distribution with known mean vectors μ_A and μ_B , and with known covariance matrices Σ_A and Σ_B .

A fundamental assumption in the models reviewed by Cole (1973) is that the measurements of the applicants are independently and identically distributed random variables. These models do not make use of the ordered scores of individuals, which is the starting point in our analysis. The ordered measurements arise in many applications. For example, in the physical or biological sciences, we may have measurements on two species, and only the largest is chosen for a particular purpose. Similarly, in the selection of candidates for employment, the order statistics are used to make a selection.

More specifically, suppose that n values of x and m values of y are given; the values are random samples from continuous distributions $F_1(x)$ and $F_2(y)$ respectively. The x, y values could, for example, be thought of as test scores for two groups of students. The $m+n$ scores are pooled and jointly ranked and the top k students are picked for a shortlist for scholarships. Our concern is with the determination of the probability, $P\{r, k; n, m\}$, that exactly r students from the first group, with x -scores, appear in the shortlist.

When $F_1(\cdot) \equiv F_2(\cdot)$, then r has a hypergeometric distribution and

$$P\{r, k; n, m\} = \binom{n}{r} \binom{m}{k-r} / \binom{n+m}{k}.$$

For the interesting special case of choosing a single candidate, that is, $r = k = 1$,

$$P\{1, 1; n, m\} = P\{x_{(n)} > y_{(m)}\} = n/(n+m).$$

where $x_{(1)} \leq \dots \leq x_{(n)}$ and $y_{(1)} \leq \dots \leq y_{(m)}$ are the order statistics of samples of sizes n and m from identical populations.

When n is small relative to m , this probability is small. Consequently, even when all the candidates come from identical populations, the probability that the best candidate from a small unit is chosen is small. This suggests that an individual who attends a small prestigious school may have considerably less chance of competing with an individual from a larger prestigious school. (It remains to be determined whether women or minorities generally attend smaller schools than men.)

This result also may explain the choice of one of two candidates, each rated as "the best candidate we have had in the last ten years," where the only difference is in the size of the pool from which each individual is drawn.

We study this model for general $F_1(x)$ and $F_2(y)$. Numerical computations can be made with the aid of Theorem 1. In particular, we consider the case where x and y have normal distributions with a common variance 1, but different means, and provide some tables of probabilities for selected sample sizes, length of shortlist, and values of the mean difference μ in the two normal populations. What this points out is the relationship between differences in means versus differences in sample sizes.

2. PROBABILITIES

2.1 Calculation of probabilities for identical parent populations.

Formally, the problem can be stated as follows. Suppose $x_{(1)} \leq x_{(2)} \leq \dots \leq x_{(n)}$ are the order statistics of a sample of size n from $F_1(x)$ and $y_{(1)} \leq y_{(2)} \leq \dots \leq y_{(m)}$ are the order statistics of an independently chosen sample of size m from $F_2(y)$. The two samples are pooled and ranked, and we want to determine $P(r, k; n, m)$, abbreviated P^* , which is the probability that r of the x -values are found in the top k rankings.

The process of recruiting usually involves the reduction of a list of candidates to a short list of k candidates. Let $E(n, m; k)$ denote the event that the best x -candidate with score $x_{(n)}$ is included in the top group of k candidates; thus at least one x -value is in the list. Then $P\{E(n, m; k)\} = 1 - P(0, k; n, m) = 1 - \{m(m-1)\dots(m-k+1)\}/\{(m+n)(m+n-1)\dots(m+n-k+1)\}$, which can also be written

$$P\{E(n, m; k)\} = \left[\binom{n+m-1}{n-1} + \binom{n+m-2}{n-1} + \dots + \binom{n+m-k}{n-1} \right] / \binom{n+m}{n}. \quad (2)$$

This formula arises naturally from considering the probability that $x_{(n)}$ is the top of the list, then that $x_{(n)}$ is second, and so on to the probability that $x_{(n)}$ is the k -th largest.

A numerical example may be informative. Suppose that there are $n = 3$ women candidates and $m = 25$ men candidates, for which a short list of k candidates is to be chosen. The probability, P , that at least one woman will be a finalist is, for $k = 1(1)10$,

| | | | | | | | | | | |
|------|------|------|------|------|------|------|------|------|------|------|
| $k:$ | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
| $P:$ | .107 | .206 | .298 | .382 | .459 | .530 | .594 | .652 | .762 | .809 |

This shows that with these values of m and n we need a short list of size at least $k = 6$ in order to guarantee that the probability of at least one woman being included in the short

list is at least 0.5. Such a computation provides a guide whether the candidate from the smaller group has an opportunity to be chosen on the short list.

2.2 Calculation of $P\{r, k; n, m\}$ in the general case.

When $F_1(\cdot) \neq F_2(\cdot)$ the probability P^* cannot be found from a simple combinatoric argument. We calculate P^* by considering the relationships between the ranked x and y values. The result is stated in Theorem 1 below.

It is intuitively more appealing to relabel the x and y sets as follows. Let $X_1 = x_{(n)}, X_2 = x_{(n-1)}, \dots, X_n = x_{(1)}$ and let $Y_1 = y_{(m)}, Y_2 = y_{(m-1)}, \dots, Y_m = y_{(1)}$, so that X_1 is the largest x , X_2 is the second largest, and so on, and similarly for the Y values. Suppose, to fix ideas, that $n = 8$, $m = 10$, and the shortlist has length $k = 5$. Then, in ascending order the values might finish as

$$\dots Y_4 X_3 Y_3 X_2 X_1 Y_2 Y_1$$

giving $r = 2$ values X in the top $k = 5$ values. For r to be equal to 2, it must be true that $X_2 > Y_4$, for if not there would be at least 4 Y -values in the top 5; also it must be true that $Y_3 > X_3$, or there would be 3 X -values in the top 5.

Applying the above argument in general leads to Theorem 1.

Theorem 1. If $x_{(1)} \leq \dots \leq x_{(n)}, y_{(1)} \leq \dots \leq y_{(m)}$, then

$$P\{r, k; n, m\} = P\{x_{(n+1-r)} > y_{(m+r-k)}\} - P\{x_{(n-r)} > y_{(m+r-k+1)}\}. \quad (3)$$

Proof. By an analysis as given earlier, to find exactly r X -values in the top k values we must have the events $\mathcal{E} : X_r > Y_{k+1-r}$ and $\mathcal{F} : Y_{k-r} > X_{r+1}$ jointly true. Thus $P^* = P\{\mathcal{E} \cap \mathcal{F}\} = P\{\mathcal{E}\} - P\{\mathcal{E} \cap \bar{\mathcal{F}}\} = P\{\mathcal{E}\} - P\{\bar{\mathcal{F}}\}$, where $\bar{\mathcal{F}}$ denotes the complement of \mathcal{F} ; the last equality follows because \mathcal{E} contains $\bar{\mathcal{F}}$. Thus

$$P^* = P\{X_r > Y_{k+1-r}\} - P\{X_{r+1} > Y_{k-r}\}.$$

which completes the proof. ||

2.3 Calculations.

A calculation such as $P\{x_{(n+1-r)} > y_{(m+r-k)}\}$ is difficult to make accurately, since it involves densities of two families of order statistics. However, if the moments of the order statistics are known, an excellent approximation can be found as follows.

Suppose $K_j(x)$ denotes the j -th cumulant of a variable x . Let $w = x_{(s)} - y_{(t)}$; then, because $x_{(s)}$ and $y_{(t)}$ are from independent samples, we have

$$K_j(w) = K_j(x_{(s)}) + (-1)^j K_j(y_{(t)}). \quad (5)$$

If the moments (or cumulants) of $x_{(s)}$, $y_{(t)}$ are known or can be calculated, the first four cumulants of w can be found, and a Pearson curve fitted to the distribution of w ; then $P\{w > 0\}$ can be easily calculated, as required for Theorem 1.

2.4 Normal parent populations.

We illustrate these computations for the case where $F_1(x)$ is the $\mathcal{N}(\mu, 1)$ distribution, and where $F_2(y)$ is the $\mathcal{N}(0, 1)$ distribution: Thus the distributions of x and y are normal, differing only in means. Let $x = z + \mu$ so that $z = \mathcal{N}(0, 1)$, and let $x_{(s)} = z_{(s)} + \mu$. Then $P\{x_{(s)} > y_{(t)}\} = P\{y_{(t)} - z_{(s)} < \mu\}$. The moments of $y_{(t)}$ and $z_{(s)}$ are extensively tabulated (Harter, 1961) or can easily be calculated numerically. These have been used to determine P^* as described above, for various values of m , n , k , r , and μ . Table 1 records $P_{\mathcal{N}}^*(r, k; n, m; \mu) = P\{r$ values of x in shortlist of length $k\}$, when there are n values of x and m values of y ; x has distribution $\mathcal{N}(\mu, 1)$ and y has distribution $\mathcal{N}(0, 1)$. The values of n are 5, 8, 12, 15, 20, 30; $m \geq n$, and $P_{\mathcal{N}}^*(r, k; n, m; \mu)$ is abbreviated $P_{\mathcal{N}}^*$. Since it is easily shown that $P_{\mathcal{N}}^* = P_{\mathcal{N}}^*(k-r, k; m, n; -\mu)$, Table 1 can easily be used when $n > m$. For example, suppose that we have $n = 20$ women and $m = 10$ men, with a shortlist of length $k = 4$; the probability of exactly 3 women, when the women's mean score exceeds the men's by 0.2 times the common standard deviation, is

$$P_{\mathcal{N}}^*(3, 4; 20, 10; 0.2) = P_{\mathcal{N}}^*(1, 4; 10, 20; -0.2) = 0.446.$$

There will often be special interest in the case when n is small. Table 2 gives values of $P_{\mathcal{N}}^*(r, k; n, m; \mu)$ for all combinations n, m where $n = 1, 2, 3$, and 4 and $m = 10, 15, 20, 30$.

2.5 A check on numerical accuracy.

When $\mu = 0$, the distributions of x and y are identical and $P_{\mathcal{N}}^*$ can be found using the hypergeometric distribution in (1). This provides a check on the accuracy of Tables 1 and 2. For example, for $n = m = 5$, $k = 2$, $P_{\mathcal{N}}^* = 2/9, 5/9, 2/9$ for $r = 0, 1, 2$ respectively. This is exactly as in Table 1. Table 3 gives a selection of values of $P_{\mathcal{N}}^*$ calculated, for $r = 0$, by the hypergeometric formula, and also those given by Table 1. It can be seen that the Pearson curve fitting gives excellent results. Although this is a check only in the middle section of the table, past experience suggests that the Pearson curves will give very close approximations to true distributions when, as here, these do not have steep densities (Solomon and Stephens, 1978). A further check will be given below.

2.6 Use of Tables 1 and 2 with other normal populations with equal variances.

Suppose x now has a normal distribution, $N(\mu_1, \sigma^2)$, and y has a normal distribution $N(\mu_2, \sigma^2)$, and we again want $P\{\text{there are } r \text{ values of } x \text{ in the shortlist of length } k\}$, now called $P_{\mathcal{N}}^{**}$. Suppose $u_{(i)} = (x_{(i)} - \mu_1)/\sigma$ and $v_{(i)} = (y_{(i)} - \mu_2)/\sigma$; then $P\{x_{(s)} > y_{(t)}\} = P\{x_{(s)}/\sigma > y_{(t)}/\sigma\} = P\{v_{(t)} - u_{(s)} < \mu\}$, where $\mu = (\mu_1 - \mu_2)/\sigma$. Since $v_{(1)}, u_{(s)}$ are order statistics from a standard normal distribution, probabilities of the last type can be used in Theorem 1 to give $P_{\mathcal{N}}^{**} = P_{\mathcal{N}}^*(r, k; n, m; \mu)$. Thus Tables 1 and 2 can be used to find values $P_{\mathcal{N}}^{**}$ for normal parent populations with different means but the same variance.

2.7 Different normal populations, with $n = 1$, $k = 1$.

This corresponds to the situation in which the single X -value is the largest of all the values. For this situation existing tables for multivariate analysis can be used, and probabilities can be found, for the more general problem where the X -value comes from a completely different normal distribution from that of the Y -values. Suppose X is $\mathcal{N}(\mu + \Delta, \sigma_1^2)$ and suppose the Y -values come from $\mathcal{N}(\mu, \sigma_2^2)$. Then the probability P^* that the X value is the largest of all the values can be expressed as $P^* = P\{X - Y_1 > 0, X - Y_2 > 0, \dots, X - Y_n > 0\}$. The typical variable $W_i = X - Y_i$ is $\mathcal{N}(\Delta, \sigma^2)$, where $\sigma^2 = \sigma_1^2 + \sigma_2^2$, and the derived variable $Z_1 = (W_i - \Delta)/\sigma$ is $\mathcal{N}(0, 1)$. The Z_i are equi-correlated with correlation coefficient $\rho = \sigma_1^2/\sigma^2$. Then

$$P^* = P(Z_1 > c, Z_2 > c, \dots, Z_n > c).$$

where $c = -\Delta/\sigma$.

Gupta (1963, Table II) has given a table from which P^* may be found. Gupta's table gives values of $G(H) = P(Z_1 < H, Z_2 < H, \dots, Z_n < H)$ for various ρ and H , and clearly $P^* = G(-c)$.

Example 1. We first use Gupta's table to make a check on our Table 2. Suppose $n = 1$ and $m = 10$, the shortlist has length $k = 1$, the excess in mean for X is $\mu (= \Delta) = 0.3$, and we want $P^* = P\{r = 1\}$, given in Table 2 as 0.142. In our table, $\sigma_1^2 = \sigma_2^2$, so $\rho = 0.5$; also $c = -\Delta/\sigma = -0.3/\sqrt{2} = -0.212$. We enter Gupta's Table II at $H = -c = 0.212$, and $N (= \text{our } m) = 10$. Interpolation in the table gives $G(0.212) = 0.142$, as in our Table 2. If $\mu = 1$, then $c = -0.707$; Table II gives $G(0.707) = 0.323$, as in our Table 2.

Example 2. Suppose again $n = 1$, $m = 10$, $k = 1$, but now $\sigma_1^2 = 1.5\sigma_2^2$. Then $\sigma^2 = 2.5\sigma_2^2$, and $\rho = 0.6$. Suppose $\Delta = 0.3\sigma_2$, so that $c = -0.3\sigma_2/\{(2.5)^{1/2}\sigma_2\} = -0.190$. Entering Table II with $\rho = 0.6$, $N = 10$, $H = 0.190$ gives $P^* = 0.468$. The checks given here, together with the remarks in Section 2.5, suggest that Tables 1 and 2 will be accurate enough for most practical purposes.

2.8 Mean exceedance needed to obtain at least one X .

Table 2 can be extended, and interpolation used, to answer the question: how large must μ be in order to obtain at least one X on the shortlist, with a certain probability, say $P\{W\}$? This would often be of interest if there are few X values compared with the number of Y values. Table 3 gives values of μ for $n = 1, 2, 3, 4$ and $m = 10, 15, 20, 30$, to ensure *at least one* X in the list of length k , with probability $P\{W\} = 0.80$, or 0.90, or 0.95, or 0.99. Recall that μ represents the exceedance in (mean/standard deviation) of X over Y , when both have normal populations and the same standard deviation.

Example 3. Suppose there is a single ($n = 1$) minority candidate, say, and $m = 10$ non-minority candidates. Using Table 3, the mean of the minority candidate would have to be 2.05 standard deviations above the mean of the non-minority candidate to ensure, with probability 0.90, that the minority candidate would be on a short list of size 3. The mean is lowered from 2.05 standard deviations to 1.76 standard deviations if the short list is of size 4 instead of size 3: that is, the discrepancy between the two groups diminishes as the size of the short list increases.

3. FURTHER DISCUSSION

A typical situation where calculations similar to the above can be used is as follows. Suppose an advertisement for a vacancy yields 18 candidates consisting of 3 women and 15 men. As a first step the search committee will prepare a shortlist of 3 individuals who are to be interviewed. If all individuals are from the same parent population of scores, then the probability $P\{W\}$ that at least one woman will be a finalist is 0.442 from (1) or (2), or from Table 2. When the populations have different means it is interesting to know how much greater must be the mean of the women to ensure, say a probability $P\{W\}$ of 0.90. From Table 4, with $n = 3$, $m = 15$, $k = 3$, $P = 0.90$, we see that the mean of the women's distribution must exceed the men's mean by 1.15σ , where σ is the common standard deviation, to achieve a $P\{W\} = 0.90$.

APPENDIX

In this Appendix we provide more extensive tables than the condensed versions included in the body of the paper.

Table 1. Selected values of the probability that r out of n candidates from a $\mathcal{N}(\mu, 1)$ population, and $k - r$ out of m candidates from a $\mathcal{N}(0, 1)$ population, are chosen on a short list of length k .

Table 2. Selected values of the probability that r out of n candidates from a $\mathcal{N}(\mu, 1)$ population, and $k - r$ out of m candidates from a $\mathcal{N}(0, 1)$ population, are chosen on a short list of length k . (Case n small.)

Table 3. Value of μ , the excess mean in a $\mathcal{N}(\mu, 1)$ population over a $\mathcal{N}(0, 1)$ population to ensure with probability P that at least 1 out of n candidates from the $\mathcal{N}(\mu, 1)$ population and $k - 1$ out of m candidates from the $\mathcal{N}(0, 1)$ population is chosen on a short list of length k .

Table 1. Selected values of the probability that r out of n candidates from a $\mathcal{N}(\mu, 1)$ population, and $k - r$ out of m candidates from a $\mathcal{N}(0, 1)$ population, are chosen on a short list of length k .

Table 2. Selected values of the probability that r out of n candidates from a $\mathcal{N}(\mu, 1)$ population, and $k - r$ out of m candidates from a $\mathcal{N}(0, 1)$ population, are chosen on a short list of length k . (Case n small.)

TECHNICAL REPORT NO. 430

20. ABSTRACT

Let $x_{(1)} \leq \dots \leq x_{(n)}$ and $y_{(1)} \leq \dots \leq y_{(m)}$ be samples of order statistics from two populations F_1 and F_2 , respectively. When the scores, say, are pooled and ordered, we address the question "what is the probability that the r largest x order statistics appear on a shortlist of k individuals?" This question underlies the selection of students, or of candidates for a job, and has implications in the selection process. We study this model for general F_1 and F_2 . Tables are given to calculate probabilities when F_1 and F_2 are normal distributions that differ only by location, and also when F_1 and F_2 are normal distributions with different means and variances, but there is only one x -value.
